

Throughout this project there were 5 major interactions I had with ChatGPT. The following is the link to the chat: <https://chatgpt.com/share/6a35dfe4-8c90-83ea-a6ca-b4943fa80708>

## **Prompt 1**

My Prompt:

"I am trying to create a prototype for a smart watch. There will be two pages for this prototype, one page presents two analog clocks with different sizes on top of each other. There is no need for functionality on these clocks. The second page shows the current time in our time zone in a digital form. This clock works in real time. There are two buttons, left corresponding to the analog page and right corresponding to the digital page, and both buttons must be present at the same time. Firstly, can you confirm the structure of this template and tell me what my next steps should be?"

AI Response:

The AI confirmed that my HTML template was structured correctly and suggested creating a CSS section, building separate analog and digital pages, using React state to switch between pages, adding navigation buttons, and using a timer to update the digital clock in real time. It also pointed out that the React code would need to be placed inside a `<script type="text/babel">` section.

How It Helped:

This interaction helped me understand how to organize the project before writing code. It gave me a step-by-step plan for building the smartwatch prototype and showed me how the different components would work together. I also learned where React code belongs within the HTML document and how Babel is used to process React code in the browser.

## **Prompt 2**

My Prompt:

"Right now nothing is appearing even though everything looks right on react? Any solutions?"

AI Response:

The AI explained that React components must be rendered into the root element and suggested creating a simple test component to verify that React was working correctly. It also recommended checking the browser console for errors and ensuring that the render function was being called correctly.

How It Helped:

This interaction helped me troubleshoot my React setup and understand how components are rendered. By testing with a simple component, I was able to verify that my environment was working before continuing development. I learned that importing React libraries alone is not enough; components must be explicitly rendered to appear on the page.

### **Prompt 3**

My Prompt:

"I have been working on the functionality of the buttons and clicking the buttons does nothing."

AI Response:

The AI explained that the buttons most likely did not have onClick functionality attached to them. It suggested using a React state variable to keep track of the current page and using button click events to change that state. The AI also explained how conditional rendering could be used to display either the analog page or the digital page depending on the current state.

How It Helped:

This interaction helped me understand how React state and event handling work together. I learned that buttons need event handlers to perform actions and that updating state can be used to control what content is displayed on the screen. This allowed me to successfully implement navigation between the analog and digital watch pages.

### **Prompt 4**

My Prompt:

"Currently this is my DigitalPage function: [code shown]. Its not working."

AI Response:

The AI identified that I was trying to display a JavaScript Date object directly by writing {time}. It explained that the date needed to be converted into a readable string using time.toLocaleTimeString(). It also suggested adding cleanup to the useEffect function by returning a function that clears the interval.

How It Helped:

This interaction helped me fix the digital clock page so that the current time displayed correctly. I learned that React cannot directly display a Date object as normal text and that it must be formatted first. I also learned why clearing intervals is important when using setInterval() inside useEffect, because it prevents unnecessary timers from continuing to run.

### **Prompt 5**

My Prompt:

"How would i go about making the hands? Dont write any code yet, just give me any ideas"

AI Response:

The AI suggested creating the clock hands as thin rectangles positioned in the center of the clock face. It also recommended making the hour hand shorter and thicker than the minute hand and using CSS transforms to rotate them.

#### How It Helped:

This interaction helped me decide how to visually represent the analog clock hands without needing complex functionality. It provided a simple and effective design approach for the prototype and taught me that common interface elements can often be created using basic HTML and CSS rather than relying on images.
